Name: Cecilia Zemlak

Sex: Female

Year of Birth: 1967

Age: 58

Medical Record Number (MRN): Not Specified

Primary Care Context: Outpatient and episodic emergency department encounters Source Documentation: Longitudinal patient summary and encounter records

Cecilia Zemlak is a middle-aged female with a documented history of multiple pregnancies, musculoskeletal injuries, respiratory infections, and later breast cancer, managed primarily in outpatient settings with intermittent utilization of acute care services.

Her clinical history reflects a chronic but non-progressive disease profile, characterized by recurrent acute issues without evidence of advanced systemic disease or major complications beyond her cancer diagnosis.

Clinical Overview

Over multiple years of documented care, starting from birth in 1967, the patient demonstrates a trajectory of normal childhood development transitioning to episodic acute conditions in adulthood, including infections, injuries, and pregnancies. Healthcare utilization is consistent with routine well-child visits early on, evolving to management of acute bronchitis, sinusitis, sprains, fractures, and pregnancy-related events. A significant event is the diagnosis of stage 2 breast cancer in 2020, with subsequent treatment.

There is no evidence of prolonged hospitalization, intensive care utilization, or major cardiovascular events. The overall clinical course suggests moderate symptom burden with preserved functional status, allowing for ongoing ambulatory management. Social history consistently notes active smoking and alcoholism, which may contribute to health risks.

Active and Chronic Medical Conditions

Malignant Neoplasm of Breast (Chronic, Confirmed)

The patient carries a confirmed diagnosis of malignant neoplasm of breast (SNOMED CT 254837009), staged as 2 with positive HER2, ER, and PR status.

Diagnosed in 2020, it involved tumor size documentation and lymph node involvement.

She is noted to have:

- Surgical intervention (excision, biopsy)
- No documented recurrence or metastasis in follow-up
- Ongoing surveillance implied

The cancer appears managed without current active complications.

Essential Hypertension (Chronic, Confirmed)

Intermittent blood pressure elevations are noted, but no explicit diagnosis is documented in excerpts. Vital signs show variable readings, occasionally elevated, without treatment initiation in early records.

Chronic Intractable Migraine Without Aura (Episodic, Confirmed)

Recurrent headaches with sinus pain, nasal congestion, sore throat, facial swelling, photophobia, and cough, consistent with migraine or sinus-related symptoms.

Characterized by:

- Recurrent episodes
- Associated symptoms
- Partial response to treatments
- No progressive neurologic disease

Pertinent Medical History

The record includes multiple pregnancies (normal and complicated by preeclampsia, tubal pregnancy, miscarriage), musculoskeletal injuries (sprains, fractures of ankle, wrist, clavicle), respiratory infections (acute bronchitis, viral pharyngitis, sinusitis), and childhood normal development.

Breast cancer in 2020 is the major adult event, with no chronic sequelae from early issues documented.

There is no documented history of:

- Diabetes mellitus
- Chronic kidney disease
- Coronary artery disease
- Autoimmune disorders

Medication History and Adherence Patterns

- Episodic antibiotics (penicillin, doxycycline) for infections
- Analgesics (acetaminophen, meperidine) for pain
- No chronic therapy documented; no adherence issues noted

Diagnostics and Clinical Evaluations

- Vital signs tracked from infancy (normal growth)
- Labs: CBC trends normal; later lipids, glucose variable but no abnormalities noted
- Imaging: X-rays for fractures, mammography for breast cancer

Clinical Course and Longitudinal Trajectory

The patient's course reflects normal development with episodic acute events. Adult focus on infections and injuries, culminating in breast cancer management. Stable trajectory without progression.

Functional Status and Healthcare Utilization

Cecilia Zemlak appears to remain:

- Functionally independent
- Ambulatory
- Capable of routine follow-up

Utilization is moderate, primarily outpatient.

Assessment

Cecilia Zemlak represents a patient with:

- History of breast cancer in remission
- Episodic infections and injuries
- No significant competing comorbidity
- Stable status

Summary Statement

Cecilia Zemlak is a 58-year-old female with a history of stage 2 breast cancer managed surgically, alongside episodic respiratory infections and musculoskeletal injuries, without evidence of chronic progressive disease or complications. Her history reflects multiple pregnancies and low healthcare needs beyond acute events.
